1. Thank the audience for being awake.

Overview/History/Philosophy

Goal: Introduce Coleman-de Shalit's regulator and show a relation to p-adic L-functions. Big picture: Regulators are maps from K-groups / motivic cohomology to absolute Hodge cohomology (Deligne-Beilinson /

syntomic). They relate to special values of L-functions.

- . Beilinson Define regulators (+Bloch and many more). Deligne-Beilinson cohomology is absolute Hodge.
 - Coleman-de Shalit Construct a ρ-adic analogue
 - · Fontaine-Messing Syntomic cohomology
 - · Gras Rigid syntomic cohomology
 - . Besser Coleman integrals compute regulators from K-theory

to rigid syntomic cohomology . Bannai - Rigid syntomic cohomology is absolute Hodge coh.

The paper is a little ad hoc, so it is interesting to note that subsequent work has placed their regulator in a broader framework.absolute hodge means derived hom in derived cat of mhs

of the above in an ad hoc wayso a posteriori everything we do here is

"right".

Beilinson regulators (Complex theory)

Beilinson regulators (Complex theory)

Let C/\mathbb{C} be a smooth complete curve, $f,g\in\mathbb{C}(C)^{\times}$. Beilinson defines

 $\epsilon_{\omega,C}(f,g)(\omega) = \frac{1}{2\pi i} \int_{C(\mathbb{C})} \log |g|^2 \overline{d} \log f \wedge \omega$ the relation to K-groups comes via $K_2(\mathbb{C}(C)) = \mathbb{C}(C)^{\times} \otimes \mathbb{C}(C)^{\times}/(f \otimes 1 - f).$

and $r_{N,C}$ satisfies this relation.

Fix E/κ be an elliptic curve with CM by \mathcal{O}_κ , κ a CM field of class number 1. Let $\mathbb{V}=\mathbb{V}_{E/\kappa}$ be the associated Grossencharacter, p be a prime that splits in κ , $p=p\overline{p}$. ω an invariant differential. Proposition (Bloch, Robritch, Doninger-Wingsberg) $\epsilon_{\kappa,E}(f,g)(\omega) = c_{\ell,g}\Omega \, L_{\infty}(E,0), \, c_{\ell,g} \in \mathbb{Q}$

Relation to L-values

(L_ $_{\infty}$ includes Gamma factors), and there exists f,g with $c_{f,g}\neq 0.$

Relation to L-values

One very interesting aspect of this definition is the relation to the L-function of an elliptic curve E.

2018-10-29	Coleman-de Shalit's <i>p</i> -adic regulator
	<i>p</i> -adic version

There is a p-adic analogue of the right hand side:

```
\label{eq:prob_equation} \begin{split} & \text{paid}_{\text{evention}} \text{ we associate a conscioud period-pair-class to } \times \\ & (0.10, )_{\text{ev}} \in (\mathbb{C}^{n} \times \mathbb{C}_{p}^{n}) \overline{\mathbb{Q}}^{n} \text{ so that} \\ & \text{Theorem (Matt., Manine Volish)} \\ & \text{Theorem (Matt., Manine Volish)} \\ & \text{Theorem (Matt., Manine Volish)} \\ & \text{Will, So about manual part of all } [1 - \Omega_{\text{event}}^{n}(1)] \text{ so that it is } \\ & \text{Goussel-howarts of conductor disclosing g with infinity types (i.e.)} \\ & k \geq 1, \mathcal{S} \\ & L_{\text{exp}}(e^{-1}, a) = \Gamma(a + b) \prod_{i=1}^{n} [1 - e^{-1}(i) \operatorname{Non}^{-1})^{-1} \\ & L_{\text{exp}}(e^{-1}, a) = \Gamma(a + b) \prod_{i=1}^{n} [1 - e^{-1}(i) \operatorname{Non}^{-1}]^{-1} \\ & \text{so have} \\ & \mathbb{Q}_{k}^{-1} k_{2k}(e^{-1}) = \Omega^{-1}(1 - p^{-1}(i)) \| k_{-k}(e^{-1}, b) \in \overline{\mathbb{Q}}. \end{split}
```

p. adic engulators ZCan envolve $s_{-L} \in s_{-L}(\ell', g) = \sum_{i \in G(G)} \operatorname{ord}_{i}(g) F_{F_{-L}}(b)$ where $F_{F_{-L}}$ satisfies $\tilde{\phi}(uf) = \tilde{\phi}(ug) f_{-L}^{(k)}(b)$ Even without $p. adic \tilde{\phi}$ one can just try by fine $F_{F_{-L}}$ satisfying $\tilde{\phi}(f) = \frac{1}{2} \int_{0}^{\infty} \int_{0}^{\infty}$

∟p-adic regulators?

So we have a p-adic L-function and p-adic period, can we define a p-adic regulator and obtain a similar theorem with $L_p(\Psi)$? The first step in this process is to rephrase the regulator pairing asfor which

$$F(P) = \log |f(P)|^2 \int_{-\infty}^{P} \omega + smooth$$

near $P_0 \in |\operatorname{div} f|$. We will see that even without a p-adic ∂ we can solve

$$\mathrm{d}F_{f,\omega} = \log f \cdot \omega$$

to get a candidate analogue of r_{∞} , the proof is in the pudding though, some relation to the L-value.

Besser does have a padic partial bar though?!

_p-adic tools (Coleman integration)

 ρ -adic tools (Coleman integration) Let $K = C_{\rho} - \overline{G}_{\rho}$, $R = C_{K}$, k = R/m. We will work with 1-dimensional rigid spaces (curves) over K. We fix a branch of the ρ -adic logarithm by: $K'' \rightarrow K$.

> It is always possible to integrate rigid 1-forms locally on a disk: given ω we have a local expression in terms of a convergent power series $\omega \circ \rho = \sum a r_i' dr$

 $\omega|_D = \sum_i a_i t^i dt$

which can be integrated formally (up to a constant). Let X/O_X be a smooth projective curve, if $Y\subseteq X$ smooth affine open, then in the special fibre $X_k \sim Y_k = \{e_1, \dots, e_b\}.$

What is hard is to integrate globally, iteratively and include $\int \frac{d^2 f}{2}$

If we want to find an analogue of the above picture we need a p-adic definition of integrals such as We are trying to define a p-adic

$$\int \log(f) \cdot \omega$$

public tools (Coloman integration)

We then remove rigid disk around e_i . V_i is locally given by \bar{b} so we can take the rigid subspace U_i . Usually diffined by |h| > r and the underlying affined is $V_{R} = \bigcup_{i \in I} E_i(v_i)$. We have $U = \lim_{i \in I} U_i$ and upsics of overconvergent functions and 1-forms $A(U_i) = \lim_{i \in I} A(U_i)$. Let V be an $A(U_i) = \lim_{i \in I} A(U_i)$.

 $\sqsubseteq p$ -adic tools (Coleman integration)

The problem comes when trying to piece these together, the discs are disconnected, there are no overlaps where we can match up values of our integral, we need more structure to find an integral unique up to a single global (additive) constant.

The additional structure we will use is the Frobenius coming from the reduction mod p.

∟p-adic tools (Coleman integration)

Here's a theorem which is needed in general, but technically unnecessary: One can imagine two different ways of computing a Coleman integral, picking a frobenius lift in a versatile but "arbitrary" way, using existance in theory or making some simple choice in practice. In some situations there are canonical Frobenius lifts, perhaps an algebraic lift of Frobenius.

Our final theory should be invariant under our choice, so we should be able to use a widely applicable computational approach à la Balakrishnan-Bradshaw-Kedlaya. Or use a lift coming from some specific structure and get the same answer.

2018-10-29

Coleman-de Shalit's p-adic regulator

Theorem (Coleman integration) $There is a subspace M(U) of A_{loc}(U), which we call the space of Coleman functions, and linear map (integration), which we denote by <math>\int$ or by $\omega \mapsto F_{\omega'}$ from $M(U) \otimes_{\mathcal{M}(U)} \Omega(U)$ to $M(U)/C_{g'}$.

The map f is characterized by three properties:

1. It is a primitive for the differential in the sense that $\mathrm{d}F_\omega=\omega$. 2. It is Frobenius equivariant $F_{\phi^*\omega}=\phi^*F_\omega$.

3. If $g \in A(U)$, then $F_{dg} = g + \mathbb{C}_p$. We also have properties such as:

 $f \in M(U)$

vanishes on one residue disk, then f is identically zero.

The space M(U) is constructed iteratively $M(U) = \bigcup_a A_o(U)$ with each step being obtained as functions you get by integration from the amplitude.

The p-adic regulator

2018-10-29

. If $a \in |\operatorname{div}(f)| = C \setminus U$ then we can fix R_a a rigid disc around a, and $V_a = R_a \setminus \{a\}$. On V_a we have

$$\int \log(f)\omega = \log(f) \int \omega - \int \left(\frac{\mathrm{d}f}{f} \int \omega\right)$$

we choose $\int \omega$ to vanish at a, so this is a function which differs from $F_{f,\omega}$ by a constant.

Doing this extends $F_{f,\omega}$ to a function on C(K) rather than just in $A_2(U)$.

 ☐ The regulator

Definition (The ρ -adic regulator). Take f, g, ω as before defined over k, then define $r(f,g)(\omega) = -\int_{(g)} \log(f)\omega = -\sum_{b \in C(K)} \operatorname{ord}_b(g)F_{f,\omega}(b) \in \overline{k}$ Theorem (Coleman-de Shalit)

 $r_C(f,g)$ is a skew-symmetric bilinear pairing on $\overline{k}(C)^{\times}$ that

 factors through K₁(\overline{k}(C)) 2. depends only on div(f), div(e)

The regulator

- is Gal(k/k) equivariant
- 4. for finite morphisms of complete non-singular curves /k $u: C' \rightarrow C$ we get $r_{C'}(u^*f, u^*g) = u^*r_C(f, g)$.

which is well defined as (g) has degree 0.giving

$$r_C \colon \mathcal{K}_2(\overline{k}(C)) \to \mathsf{Hom}(H^0(C,\Omega^1_{C/\overline{k}}),\overline{k}).$$

Comparison of the p-adic and C theories

We now move to a very special situation, where the above regulators can be shown to be related to L-values. $C = E/\kappa$ will be an elliptic curve with CM by \mathcal{O}_K . $\Psi = \Psi_{E/\kappa}$ the corresponding Grossencharacter with conductor f and assume

 $\mathsf{w}_{\mathsf{f}} = \#\{\zeta \in \mu(K) : \zeta \equiv 1 \pmod{\mathsf{f}}\} = 1.$

let ω be a x-rational invariant differential, $\mathscr L$ the period lattice of $(E,\omega).$

☐The theorem

Thoroum (Rahrlich, others!) $t_{n,\ell}(t,g) = t_{n,\ell}(t,g) = t_{n,$

The theorem

.the $c_{f,g}$ is the to the $c_{f,g}$ in the first theorem, I haven't just abused notation, this was one of the most surprising aspects of this theorem to me, personally my main goal was to understand this

2018-10-29	Coleman-de Shalit's <i>p</i> -adic regulator —Proof

.see de Shalit.

We use a specific class of ℓ' is (for (a, [p) - 1), the functions $\ell(\ell) - \Theta_d(\ell) - \Delta(\ell)\Delta(e^{-1} \mathcal{L})^{-1} \frac{1}{-1} \frac{d}{d_d} (q^{(p)} - \chi(\theta))^{\alpha} \in \kappa(\mathcal{E})^{\gamma}$ whose values are elliptic units, the divisor of Θ_d is $12 \left((\text{Non} - 1) (\circ) - \sum_{x \in \mathcal{X}} (R) \right)$ and we have the distribution relation $\ell(\ell') - \prod_{x \in \mathcal{X}} \ell(\ell') + \gamma \right)$

These functions generate the set of all functions with divisors supported on torsion. We also take $g \in \kappa(E)^n$ with divisor supported on torsion and $Q \in |\operatorname{div} g| \longrightarrow f(\varrho_Q, (\varrho_Q, \varphi)) = 1$.

Take v with the a formion points surround, $X(\phi) = \mathbb{R} \cdot \sum_{P \in \mathcal{P}_{\theta}} B(P) \cdot \mathbb{I} \cdot \mathbb{Q}(\phi) = \mathbb{E} \cdot \sum_{P \in \mathcal{P}_{\theta}} B(P \cdot r)$ Take <math>D the Δ derivation that is dual to ϕ to ϕ $(\mathcal{P}_{\theta} - 1)$. Then f_{P} is the unique (up to constant) $\mathbb{E} \cdot \mathbb{Q}_{\theta} (U(\phi))$ for which $D = \mathbb{E} \cdot \mathbb{Q}_{\theta} (U(\phi))$ Then we have $D(F(\psi^{p})) = \pi \cdot (DF(\psi^{p}))$ and the distribution points are stations given

..

2018-10-29

Coleman-de Shalit's p-adic regulator

By definition $\pi=\psi(\mathfrak{p})$ is a lift of frobenius (which is algebraic!). As $F\in A_2(U_r(\mathfrak{a}))$, for some (possibly different) r close to 1 we have

$$F(\pi P) - \pi \sum_{v \in E[a]} F(P + v) \in A_2(U_r(a))$$

the above implies this is locally constant, hence constant! So we change ${\cal F}$ to get that

$$F(\pi P) - \pi \sum_{v \in E[v]} F(P + v) = 0.$$

$$\begin{split} F(x)P &= x \sum_{v \in [x]} F(P + v) = 0. \\ \text{How define} \\ F^{\pm}(P) &= F(P) - F^{-1} \sum_{v \in [x]} F(P + v) \\ \text{so that ss. } Q \in [dv_{\mathcal{G}}] \text{ is Galois conjugate to } = Q \text{ over } v: \\ r_{\mathcal{G}}(P, x) &= -\sum_{\mathcal{G}} ad_{\mathcal{G}} g^{\mu}(Q) - \sum_{\mathcal{G}} ad_{\mathcal{G}} g^{\mu}(Q) \\ \\ \Big[\frac{1}{2\pi} \Big| r_{\mathcal{G}}(P, x) = -\sum_{\mathcal{G}} ad_{\mathcal{G}} g^{\mu}(Q). \end{split}$$

We also have $\log(f)^{\#}(P) = \log f(P) - \rho^{-1} \sum_{v \in E[\tau]} \log f(P + v).$

If Q is a torsion point in $X(\mathfrak{a})$ relatively prime to \mathfrak{p} order, then de Shalit has associated a

 $\eta_{\mathcal{O}} \colon \widehat{\mathsf{G}}_m \xrightarrow{\sim} \widehat{E}$

so $Q + \eta_Q(S)$ parameterises the residue disk of Q and a $W = W(\overline{\mathbb{F}}_p)$ valued measure μ_Q on \mathbb{Z}_p^{\times} s.t.

 $\log(f)^\#(Q+\eta_Q(S))=\int_{\mathbf{Z}_p^+}(1+S)^\times\,\mathrm{d}\mu_Q(x)\in W[[S]]$

Then work of de Shalit shows that $F^{\#}(Q+\eta_{Q}(S))=\underbrace{\eta_{Q}'(0)}_{\Omega_{P}(Q)}\int_{\mathbf{Z}_{p}^{+}}^{+}(1+S)^{\times}x^{-1}\,\mathrm{d}\mu_{Q}(x)+c$ for some constant c, and that $F^{\#}(P)$ is rigid analytic on X(a)

 $\left(1 - \frac{1}{\pi p}\right) \epsilon_p(f, g) = -\sum_Q \operatorname{ord}_Q g \Omega_p(Q) \int_{\mathbb{Z}_p^2} x^{-1} d\mu_Q(x).$ We need to move to the correct group and remove the depends on Q, by identifying $G = \operatorname{Gal}(\epsilon(gp^n)/\epsilon(g)) \cong \mathbb{Z}_p^2$ so that

 $= - \sum_{\langle Q \rangle} \operatorname{ord}_Q g \Omega_{\beta}(Q) \sum_{\sigma \in \mathscr{G}/G} \int_G \Psi^{-1}(\sigma) \, \mathrm{d} \mu_{\tau(Q)}(\sigma)$

 $= - \sum_{\langle Q \rangle} \operatorname{ord}_Q g \Omega_{\beta}(Q) \int_{\mathscr{C}(g_Q)} \Psi^{-1}(\sigma) \, \mathrm{d}\mu_{\theta}(\sigma)$

eta is parameterising the residue disk around Qe is norm compatible sequence of elliptic units (question for later: an euler system?!)

```
Theorem (Cautes-Wiles) p_{n}=12(p_{n}-10na)\rho(g_{0}) where \rho(g_{0}) is the measure which defines the padic Liurction of conductor g_{0} gos removing those factors we reach Constantian element (1-(p_{0})^{-1}), g(f_{0})=\frac{1}{2}(2(0na-v^{-1}g_{0})), g(f_{0})=\frac{1}{2}(2(0na-v^{-1}g_{0})), g(f_{0})=\frac{1}{2}(1-v(0)) \log p(f_{0})
```

this isn't the exact formula we saw earlier, need to factor out a Ω_p to get something algebraic
